All electrons vs pseudopotentials Classes of Basis-set Condensed phase: Bloch's th and PBC

### All electrons vs pseudopotentials

There are two classes of electrons: *valence electrons* (participate to chemical bonds) and *core electrons* (tightly bound to the nuclei). Eventually *semi-core electrons* (close in energy to valence states to feel the presence of the environment)

#### All-electron methods

- fixed orbital basis set: core electron minimal number of basis function to reproduce atomic features, valence and semi-core more complete basis set to describe the chemical bond.
- augmented basis set. Divide the space into spherical regions around the atoms and interstitial regions and requesting that the basis functions are continuous and differentiable across the boundaries.

イロト イポト イヨト イヨト

All electrons vs pseudopotentials Classes of Basis-set Condensed phase: Bloch's th and PBC

# Pseudopotential methods

- ► Core electrons are eliminated. Nuclei effective charge Z<sub>V</sub> = Z - Z<sub>core</sub>.
- Number of electron treated explicitly is reduced
- The bare Coulomb potential is replaced by a screened Coulomb potential
- Inner solution, inside the core radius, is replaced with a smooth, node-less pseudo-wave function
- Pseudopotentials are usually chosen to be dependent on the angular momentum.

E.g. for Pt 6p orbitals are quite external and peaked at around 3.9Å, the 6s peak at around 2.4 Åand the main peak of 5d is located ate 1.3 Å.

All electrons vs pseudopotentials Classes of Basis-set Condensed phase: Bloch's th and PBC

# Classes of Basis-set

- Extended basis set: delocalized, such as plane waves, useful for condensed phase systems. Tends to be inefficient for molecular systems.
- Localized basis set: mainly centered at the atomic positions (but also at position of "ghost" atoms). Mainly used for molecular systems
- Mixed basis set: designed to take best of the two worlds (delocalized + localized). There can be some technical issues (over-completeness).
- Augmented basis set: where an extended or atom centered basis set is augmented with atomic like wf in spherical regions around the nuclei.

イロン イ部ン イヨン イヨン 三日

All electrons vs pseudopotentials Classes of Basis-set Condensed phase: Bloch's th and PBC

# Condensed phase: Bloch's th and PBC

Condensed phase: problem of choosing the size of the simulation cell. For periodic system: unit of Wigner-Seitz cell, the minimal choice that contains the whole symmetry of the system. Sometimes it is convenient to choose a larger cell to simplify description of symmetry properties. In an external periodic potential  $v(\mathbf{r}) = v(\mathbf{r} + \mathbf{a}_i)$  the wf can be written as:

$$\psi_k(\mathbf{r}) = e^{i\mathbf{k}\cdot\mathbf{r}} u_k(\mathbf{r}) \tag{1}$$

with  $u_k(\mathbf{r}) = u_k(\mathbf{r} + \mathbf{a}_i)$ .

$$\psi_k(\mathbf{r} + \mathbf{a}_i) = e^{i\mathbf{k}\cdot\mathbf{a}_i}\psi_k(\mathbf{r})$$
(2)

So that the probability density is  $|\psi_k(\mathbf{r})|^2$  is exactly the same.

イロン イヨン イヨン イヨン

 Outline

 Solving the electronic problem in practice
 All electrons vs pseudopotentials

 Pseudopotentials
 Classes of Basis-set

 Thermostats
 Condensed phase: Bloch's th and PBC

Looking at

$$\psi_k(\mathbf{r}+\mathbf{a}_i)=e^{i\mathbf{k}\cdot\mathbf{a}_i}\psi_k(\mathbf{r})$$

we notice that there is a a class of vectors  ${\boldsymbol k}$  such that

$$e^{i\mathbf{k}\cdot\mathbf{a}_i} = 1 \tag{3}$$

The reciprocal lattice vectors are defined by

$$\mathbf{a}_{\mathbf{i}} \cdot \mathbf{b}_{\mathbf{j}} = 2\pi \delta_{ij} \tag{4}$$

and

$$\mathbf{b_1} = 2\pi \frac{\mathbf{a_2} \times \mathbf{a_3}}{\Omega}; \ \mathbf{b_2} = 2\pi \frac{\mathbf{a_3} \times \mathbf{a_1}}{\Omega}; \ \mathbf{b_3} = 2\pi \frac{\mathbf{a_1} \times \mathbf{a_2}}{\Omega}$$
(5)

The reciprocal lattice vectors define the first Brillouin Zone (BZ).

æ

$$ec{b}_i = rac{2\pi}{\Omega} (ec{a}_j imes ec{a}_k)$$

Bloch's theorem indicates that it is not necessary to determine the electronic wavefunction everywhere in space. It is sufficient to know the solution in the unit cell.

Using the fact that a periodic function can be represented by a Fourier series:

$$\psi_{k}(\mathbf{r}) = e^{i\mathbf{k}\cdot\mathbf{r}} \sum_{\mathbf{G}} C_{\mathbf{k}+\mathbf{G}} e^{i\mathbf{G}\cdot\mathbf{r}}$$
(6)

where the sum is over  $G = n_1 \mathbf{b}_1 + n_2 \mathbf{b}_2 + n_3 \mathbf{b}_3$ , the reciprocal lattice vectors.

**k** is restricted to all the vectors in the first Brillouin zone. In practice calculations are done only for a finite number of **k**. The number of **k** points depends on the systems we want to study.

All electrons vs pseudopotentials Classes of Basis-set Condensed phase: Bloch's th and PBC

# Aperiodic systems: molecules, surfaces and defects

- supercell approach with PBC, making sure that required physical and chemical properties are converged with respect to the size of the supercell.
- For surfaces and molecules, e.g., introduce a a vacuum region large enough that there so interaction between images.
- For charged systems difficulties due to the electrostatic interactions (long range). A uniform neutralizing background is introduced.

소리가 소문가 소문가 소문가

- Only the chemically active electrons are considered explicitly.
- The core electrons are eliminated within the frozen-core approximation and are considered together with the nuclei as rigid non-polarizable ion cores.
- The Pauli repulsion largely cancels the attractive parts of the true potential in the core region, and is built into the therefore rather weak pseudopotentials.

<ロ> (四) (四) (注) (注) (三)

Hamann-Schlüter-Chiang pseudopotentials Bachelet, Kerker, Martin-Troulliers

# Why Pseudopotentials?

- Reduction of the number of electron in the systems, faster calculation for large systems
- Relativistic effects depending on the core electrons treated incorporated indirectly in the pseudopotentials
- In the frame of plane wave basis set: reduction of the basis set size introducing smoother functions which requires a lower cutoff
- The number of plane waves needed for a certain accuracy increases with the square of the nuclear charge.

### Norm-conserving pseudopotentials

Norm-conserving pseudopotentials conserves the normalization of the pseudo wf in the core region so that the wf outside resembles that of the all-electrons as closely as possible.

Valence and pseudo wf of a Si atom, generated according to Martin-Troullier scheme.

< E

Hamann-Schlüter-Chiang pseudopotentials Bachelet, Kerker, Martin-Troulliers

# Hamann-Schlüter-Chiang conditions<sup>1</sup>

Norm-conserving pseudos are derived from atomic reference state:

$$(T + V^{AE})|\Psi_l\rangle = \epsilon_l |\Psi_l\rangle.$$
(7)

This is replaced by the "valence electrons only"

$$(T + V^{val})|\Phi_l\rangle = \tilde{\epsilon}_l |\Phi_l\rangle.$$
(8)

Imposing the following:

- $\epsilon_I = \tilde{\epsilon}_I$  for a chosen prototype atomic configuration.
- $\Psi_l(r) = \Phi_l(r)$  for  $r \ge r_c$ .
- Norm conservation,  $\langle \Phi_I | \Phi_I \rangle_R = \langle \Psi_I | \Psi_I \rangle_R$  for  $R \ge r_c$ .
- Log derivative of  $\Phi_l$  equal to that of  $\Psi_l$ .

<sup>1</sup>Hamann-Schlüter-Chiang, *Phys. Rev. Lett.*, 43, 1494 (1979) ≧ → « ≧ →

Hamann-Schlüter-Chiang pseudopotentials Bachelet, Kerker, Martin-Troulliers

# Hamann-Schlüter-Chiang recipe

First step: the all-electron wf is multiplied by a smoothing function f<sub>1</sub> to remove strongly attractive and singular part of the potential:

$$V_l^{(1)}(r) = V^{AE}(r) \left[ 1 - f_1\left(\frac{r}{r_{c,l}}\right) \right]$$
(9)

• Then a function  $f_2$  is added in order to obtain  $\epsilon_I = \tilde{\epsilon}_I$ 

$$V_{l}^{(2)}(r) = V_{l}^{(1)}(r) + c_{l}f_{2}\left(\frac{r}{r_{c,l}}\right)$$
(10)

$$\left(T + V_l^{(2)}(r)\right) w_l^{(2)}(r) = \tilde{\epsilon}_l w_l^{(2)}(r)$$
(11)

This determines the value of  $c_l$ .

イロト イポト イヨト イヨト

Hamann-Schlüter-Chiang pseudopotentials Bachelet, Kerker, Martin-Troulliers

### Hamann-Schlüter-Chiang recipe

The valence wf is defined as

$$\Phi_{I}(r) = -\gamma_{I} \left[ w_{I}^{(2)}(r) + \delta_{I} r^{I+1} f_{3} \left( \frac{r}{r_{c,I}} \right) \right]$$
(12)

where  $\gamma_l$  and  $\delta_l$  are chosen such that  $\Phi_l(r) \rightarrow \Psi_l(r)$  for  $R \ge r_c$ . And

$$\gamma_l^2 \int |w_l^{(2)}(r) + \delta_l r^{l+1} f_3\left(\frac{r}{r_{c,l}}\right)|^2 i dr = 1$$
 (13)

イロト イヨト イヨト イヨト

3

Hamann-Schlüter-Chiang pseudopotentials Bachelet, Kerker, Martin-Troulliers

# Hamann-Schlüter-Chiang recipe

• Given  $\Phi_l$  and  $\tilde{\epsilon}_l$  the equation:

$$(T + V^{val})|\Phi_l > = \tilde{\epsilon}_l |\Phi_l > .$$

is inverted to get  $V^{val}(r)$ .

Hamann-Schlüter-Chiang chose  $f_1(x) = f_2(x) = f_3(x) = exp[-x^4]$ .

$$V_{l}^{PP}(r) = V_{l}^{val}(r) - V_{H}(n_{V}) - V_{xc}(n_{V})$$
(14)

The total atomic pseudopotential then takes the form of a sum over all angular momentum channels:

$$V^{PP}(\mathbf{r}) = \sum_{L} V_{L}^{PP}(r) \mathbf{P}_{L}(\omega)$$
(15)

where  $\mathbf{P}_{L}(\omega)$  is the projector on the angular momentum state L, defined by  $\{I, m\}$  and  $\omega$  are angular variables.

l

Hamann-Schlüter-Chiang pseudopotentials Bachelet, Kerker, Martin-Troulliers

# Bachelet-Hamann-Schlüter pseudopotentials

Bachelet et proposed an analytic form to fit the pseudos generated by Hamann-Schlüter-Chiang of the form:

$$V^{PP}(r) = V^{core}(r) + \sum_{L} \Delta V_{L}^{ion}(r)$$
(16)  

$$V^{core}(r) = -\frac{Z_{V}}{r} \left[ \sum_{i=1}^{2} c_{i}^{core} erf(\sqrt{\alpha_{i}^{core}}r) \right]$$
(17)  

$$V_{L}^{ion}(r) = \sum_{i=1}^{3} (A_{i} + r^{2}A_{i+3})exp[-\alpha_{i}r^{2}]$$
(18)

the advantage here is that this form allow an easy implementation in plane-wave code, since the Fourier transform can be also written analytically.

Hamann-Schlüter-Chiang pseudopotentials Bachelet, Kerker, Martin-Troulliers

# Kerker pseudopotentials

In the Kerker approach<sup>2</sup> psedupotentials are constructed to satisfy HSC conditions, but replacing the AE wf inside  $r_c$  with a smooth analytic function that matches the AE wf at  $r_c$ .

•  $r_c$  is generally larger than that used in HSC

The analytic form proposed by Kerker is

$$\Phi_{l}(r) = r^{l+1} exp[p(r)] \text{ for } r < r_{c,l}$$
(19)

with I-dependent cut-off radii  $r_{c,I}$  and

$$p(r) = \alpha r^4 + \beta r^3 + \gamma r^2 + \delta$$
 (20)

The method of Kerker was generalized by Troullier and Martins to polynomials of higher order<sup>3</sup> <sup>2</sup>Kerker, J. of Phys. C 13; L189 (1980) <sup>3</sup>Phys. rev. B, 43: 1993. (1991).

イロン イヨン イヨン イヨン

3

Thermostat on the electrons Nose'-Hoover chain thermostat

# Zero or small electronic gaps: thermostatted electrons

- One way to (try to) overcome the problem in coupling of electronic and ionic dynamics is to thermostat also the electrons (Blöchl & Parrinello, PRB 1992)
- Thus electrons cannot heat up; if they try to, thermostat will adsorb the excess heat
- Target fictitious kinetic energy  $E_{kin,0}$  instead of temperature
- Mass of thermostat to be selected appropriately: Too light: Adiabacity violated (electrons may heat up) Too heavy: lons dragged excessively
- Note: Introducing the thermostat the conserved quantity changes

・ロト ・回ト ・ヨト ・ヨト

Thermostat on the electrons Nose'-Hoover chain thermostat

$$M_{I}\ddot{\mathbf{R}}_{I}(t) = -\frac{\partial}{\partial \mathbf{R}_{I}} < \Psi_{0}|H_{e}^{KS}|\Psi_{0} > -M_{I}\dot{R}_{I}\dot{\mathbf{x}}_{R}$$
(21)  
$$\mu\ddot{\phi}_{i}(t) = -H_{e}^{KS}\phi_{i} + \sum_{j}\Lambda_{ij}\phi_{j} - \mu\dot{\phi}_{i}\dot{\mathbf{x}}_{e}$$
(22)

in blue are the frictious terms governed by the following equations:

$$Q_{e}\ddot{x}_{e} = 2\left[\sum_{i}\mu\dot{\phi}^{2} - E_{kin,0}\right]$$

$$Q_{R}\ddot{x}_{R} = 2\left[\sum_{I}\frac{1}{2}M_{I}\dot{R}^{2} - \frac{1}{2}gK_{B}T\right]$$
(23)
(24)

The masses  $Q_e$  and  $Q_R$  determines the time scale for the thermal fluctuations. The conserved quantity is now:

$$E_{tot} = \sum_{I} \frac{1}{2} M_{I} \dot{\mathbf{R}}_{I}^{2} + \sum_{i} \mu < \dot{\phi}_{i} |\dot{\phi}_{i} > + < \Psi_{0}| H_{e}^{KS} |\Psi_{0} >$$

$$+ \frac{1}{2} Q_{e} \dot{x}_{e}^{2} + 2E_{kin} Q_{e} + \frac{1}{2} Q_{R} \dot{x}_{e}^{2} + gK_{R} T \bar{x}_{e}^{KS} |\Psi_{0} >$$
Marialore Sulpizi Density Functional Theory: from theory to Applications

Standard Nose'-Hoover thermostat suffers from non-ergodicity problems for certain classes of Hamiltonian, so a closely related technique has been proposed, the Nose'-Hoover chain thermostat. For the nuclear part:

$$M_I \ddot{\mathbf{R}}_I = -\nabla E^{KS} - M_I \dot{\xi}_1 \dot{\mathbf{R}}_I$$
(26)

$$Q_1^n \ddot{\xi}_1 = \left[ \sum_l M_l \dot{R}_l^2 - g \kappa_B T \right] - Q_1^n \dot{\xi}_1 \dot{\xi}_2$$
(27)

$$Q_{k}^{n}\ddot{\xi}_{k} = 2\left[Q_{k-1}^{n}\dot{\xi}_{k-1}^{2} - K_{B}T\right] - Q_{k}^{n}\dot{\xi}_{k}\dot{\xi}_{k+1}(1-\delta_{kK})$$
(28)

For the electronic part:

$$\mu \ddot{\phi}_i = -H_e^{KS} \phi_i + \sum_{ij} \Lambda_{ij} \phi_j - \mu \dot{\eta}_1 \dot{\phi}_i$$
<sup>(29)</sup>

$$Q_{1}^{e}\ddot{\eta}_{1} = \left[\sum_{i}^{occ} \mu < \phi_{i} | \phi_{i} > -T_{1}^{0}\right] - Q_{1}^{e}\dot{\eta}_{1}\dot{\eta}_{2}$$
(30)  
$$Q_{l}^{n}\ddot{\eta}_{l} = 2\left[Q_{l-1}^{n}\dot{\eta}_{l-1}^{2} - \frac{1}{\beta_{e}}\right] - Q_{l}^{e}\dot{\eta}_{l}\dot{\eta}_{l+1}(1 - \delta_{lL})$$
(31)

Marialore Sulpizi Density Functional Theory: from theory to Applications

- Separate chains composed of K and L coupled thermostats are attached to the nuclear and electronic equations of motion, respectively
- Masses for the thermostats are chosen so that there overlap of the thermostat and system power spectra.

$$Q_{1}^{n} = \frac{gK_{B}T}{\omega_{n}^{2}}, \dots Q_{k}^{n} = \frac{gK_{B}T}{\omega_{n}^{2}}, \qquad (32)$$
$$Q_{1}^{e} = \frac{2T_{e}^{0}}{\omega_{e}^{2}}, \dots Q_{l}^{e} = \frac{2T_{e}^{0}}{\omega_{e}^{2}} \qquad (33)$$

 massive thermostatting method: NH chains for individual nuclear degree of freedom. Accelerate expensive equilibration periods

イロト イポト イヨト イヨト

### Energy and Momentum conservation

In micro-canonical classical molecular simulations the total energy and the total momentum are conserved.

In the case of thermostatted NVT simulations the constant of motion is:

$$E_{cons}^{NVT} = \sum_{i}^{occ} \mu \langle \dot{\phi}_{i} | \dot{\phi}_{i} \rangle + \sum_{I} \frac{1}{2} M_{I} \dot{\mathbf{R}}_{I}^{2} + E^{KS} [\{\phi_{i}\}, \{\mathbf{R}_{I}\}]$$
(34)  
+  $\sum_{I=1}^{L} \frac{1}{2} Q_{I}^{e} \dot{\eta}_{I}^{2} + \sum_{I=2}^{L} \frac{\eta_{I}}{\beta_{e}} + 2 T_{e}^{0} \eta_{1} + \sum_{k=1}^{K} \frac{1}{2} Q_{k}^{n} \dot{\xi}_{k}^{2} + \sum_{k=2}^{K} K_{b} T \xi_{k} + g K_{b} T \xi_{1}$ (35)

In micro-canonical CPMD a generalized linear momentum is conserved:

$$\mathbf{P}_{CP} = \mathbf{P}_n + \mathbf{P}_e = \sum_{I} \mathbf{P}_{I} + \sum_{i}^{occ} \mu < \dot{\phi}_i | -\frac{1}{2} \nabla_r | \phi_i > + c.c.$$
(36)

where  $\mathbf{P}_I = M_I \dot{\mathbf{R}}_I$ .

Alternative approach for clusters

### Imposing pressure: barostats

Original version from Andersen<sup>4</sup> devised to allow isotropic fluctuations in the volume of the supercell. Variable cell approach: allows structural phase transition in solids at finite temperature. Parrinello-Rahman<sup>5</sup> Built an extended Lagrangian with additional dynamical variables  $\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3$ , the primitive Bravais lattice vectors. Using the 3X3 matrix  $\mathbf{h} = [\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3]$  which define the volume  $\Omega$ , the scaled coordinates  $\mathbf{S}$  are defined by  $\mathbf{R}_I = \mathbf{h}\mathbf{S}_I$ . the normalized original orbitals are transformed according to:

$$\phi_i(\mathbf{r}) = \frac{1}{\Omega} \phi_i(\mathbf{s}) \tag{37}$$

The cell-variable extended Lagrangian is:

$$\mathcal{L} = \sum_{i} \mu < \dot{\phi}(\mathbf{s})_{i} | \dot{\phi}_{i}(\mathbf{s}) > -E^{KS}[\{\phi_{i}\}, \{\mathbf{hS}_{I}\}]$$

$$+ \sum_{i} \Lambda_{ij}(<\phi_{i}(\mathbf{s}) | \phi_{j}(\mathbf{s}) > -\delta_{ij}) + \sum_{I} \frac{1}{2} M_{I}(\overset{i}{\mathbf{s}}_{I} \overset{i}{\mathbf{h}} \overset{i}{\mathbf{h}} \overset{i}{\mathbf{s}}_{I}) + \frac{1}{2} WTr \dot{\mathbf{h}}^{T} \overset{i}{\mathbf{h}} \overset{i}{\mathbf{s}}_{I} - \sum_{i} \Omega_{i} \mathcal{O}$$

$$Matidade Subizi \qquad Density Exercised Theory to Applications$$

$$(38)$$

$$\mathcal{L} = \sum_{i} \mu \langle \dot{\phi}(\mathbf{s})_{i} | \dot{\phi}_{i}(\mathbf{s}) \rangle - E^{KS}[\{\phi_{i}\}, \{\mathbf{hS}_{I}\}]$$

$$+ \sum_{ij} \Lambda_{ij}(\langle \phi_{i}(\mathbf{s}) | \phi_{j}(\mathbf{s}) \rangle - \delta_{ij}) + \sum_{I} \frac{1}{2} M_{I}(\mathbf{S}_{I}^{\mathsf{T}}\mathbf{h}^{\mathsf{T}}\mathbf{h}\dot{\mathbf{S}}_{I}) + \frac{1}{2} W Tr\dot{\mathbf{h}}^{\mathsf{T}}\dot{\mathbf{h}} - p\Omega$$
(39)

- nine additional degrees of freedom associated with lattice vectors of supercell h.
- ► This constant-pressure CPMD reduce to constant-volume CPMD in the limit  $\dot{\mathbf{h}} \rightarrow 0$  (apart from a constant term  $p\Omega$
- ► *W* is the fictious mass that controls the timescale of the cell dynamics

・ロン ・回 と ・ ヨ と ・ ヨ と

The resulting equations of motion are:

$$M_{I}\ddot{S}_{I,u} = -\sum_{\nu=1}^{3} \frac{\partial E^{\kappa S}}{\partial R_{I,\nu}} (\mathbf{h}^{T})_{\nu,u}^{-1} - M_{I} \sum_{\nu=1}^{3} \sum_{s=1}^{3} \mathcal{G}_{u\nu}^{-1} \dot{\mathcal{G}}_{\nu s} \dot{S}_{I,s} \quad (40)$$
  
$$\mu \ddot{\phi}_{i}(\mathbf{s}) = -\frac{\partial E^{\kappa S}}{\partial \phi_{i}^{*}(\mathbf{s})} + \sum_{j} \Lambda_{ij} \phi_{j}(\mathbf{s}) \quad (41)$$

$$W\ddot{h}_{uv} = \Omega \sum_{s=1}^{3} (\Pi_{us}^{tot} - p\delta_{us})(\mathbf{h}^{T})_{sv}^{-1}$$
(42)

where the total stress tensor is:

$$\Pi_{us}^{tot} = \frac{1}{\Omega} \sum_{I} M_{I} (\dot{\mathbf{S}}_{I}^{T} \mathcal{G} \dot{\mathbf{S}}_{I})_{us} + \Pi_{us}$$
(43)

and  $\Pi_{us}$  is electronic stress tensor:

$$\Pi_{us} = -\frac{1}{\Omega} \sum_{v} \frac{\partial E_{tot}}{\partial h_{uv}} h_{vs}^{T}$$
(44)

#### Alternative approach for clusters<sup>7</sup>.

Idea: surrounding the finite cluster by a pressurizing medium described by  $N_L$  classical point particles.i (e.g. liquid of purely repulsive soft spheres). The corresponding Lagrangian is:

$$\mathcal{L} = \sum_{I} \frac{1}{2} M_{I} \dot{\mathbf{R}}_{I}^{2} + \sum_{i} \mu \langle \dot{\phi}(\mathbf{r})_{i} | \dot{\phi}_{i}(\mathbf{r}) \rangle - E^{KS}[\{\phi_{i}\}, \{\mathbf{R}_{I}\}]$$
(45)  
+ 
$$\sum_{ij} \langle \langle \phi(\mathbf{r})_{i} | \phi_{j}(\mathbf{r}) \rangle - \delta_{ij} \rangle + \sum_{\alpha} \frac{1}{2} M_{\alpha} \dot{\mathbf{X}}_{\alpha}^{2}$$
(46)  
+ 
$$-\sum_{I,\alpha} V_{C-L}(|\mathbf{R}_{I} - \mathbf{X}_{\alpha}|) - \sum_{\alpha < \beta} V_{L-L}(|\mathbf{X}_{\alpha} - \mathbf{X}_{\beta}|)$$
(47)

where  $M_{\alpha}$  is the mass of a liquid particle at position  $\mathbf{X}_{\alpha}$  and  $V_{C-L}$  and  $V_{L-L}$  are model pair potential to describe the cluster-liquid and the liquid-liquid interactions.

Alternative approach for clusters

#### How is the pressure controlled? For purely repulsive soft spheres:

$$V_{L-L}(r) = \epsilon_{L-L} \left(\frac{\sigma_{L-L}}{r}\right)^{12}$$
(48)

the equation of state gives:

$$p = \frac{N_L K_B T}{\Omega_L} \xi(\tilde{\rho}) \tag{49}$$

where

$$\xi(\tilde{\rho}) = \frac{N_L}{\Omega_L} \frac{\sigma_{L-L}^3}{\sqrt{2}} \left(\frac{\epsilon_{L-L}}{K_B T}\right)^{1/4}$$
(50)

the pressure is adjusted tuning  $\epsilon_{L-L}$ .

Marialore Sulpizi Density Functional Theory: from theory to Applications

Alternative approach for clusters

In both clusters, up to 25 GPa, a distorted but predominantly tetrahedral coordination is maintained, with no sign of a transformation to a different structure. This also holds for the case with the vacancy, even if with a higher degree of disorder.

Dramatic structural transformation occurs for Si35H36 at 35 GPa and for Si71H60 at 30 GPa. Shape changes to roughly spherical and the tetrahedral coordination is no longer dominant. (In accord with exps.)

Distributions of the SiSi distances for Si71H60

イロン イヨン イヨン イヨン

æ

The change in coordination and shape is accompanied by a change in the electronic properties.

There is a clear qualitative trend toward metallicity at high pressure.

Time evolution of the KohnSham energy gap of Si35H36
